AUSTRALIAN HIV OBSERVATIONAL DATABASE ANNUAL REPORT 2016

(Volume 16, Number 1: August 2016)

How do outcomes compare between women and men living with HIV in Australia? An observational study

Background: Gender differences vary across geographical settings and are poorly reported in the literature. The aim of this study published in Sexual Health [1] was to evaluate demographics and clinical characteristics of participants from the Australian HIV Observational Database (AHOD), and to explore any differences between females and males in the rate of new clinical outcomes, as well as initial immunological and virological response to antiretroviral therapy.

Methods: Time to a new clinical end-point, all-cause mortality and/or AIDS illness was analysed using standard survival methods. Univariate and covariate adjusted Cox proportional hazard models were used to evaluate the time to plasma viral load suppression in all patients that initiated antiretroviral therapy (ART) and time to switching from a first-line ART to a second-line ART regimen.

Results: Of 3,495 patients enrolled in AHOD at the time of the study with at least one follow-up visit, 210 (6%) were female (**Table 1**). Most patients initiated ART between 1999 and 2004 and protease-inhibitor anchored regimens were the most common first line regimen (42% of females and 41% males). No statistically significant differences were found in CD4 cell counts at initiation and response.

The hazard of all-cause mortality, new AIDS illness and a composite end-point were not found to be significantly different between females and males (**Table 2**). Incident rates of all-cause mortality were similar between females and males; 1.14 (0.61, 1.95) vs 1.28 (1.12, 1.45) per 100 person years, further emphasized by comparable Kaplan-Meier cumulative incidence curves (**Figure 1**). Virological response to ART was similar for females and males when measured as time to viral suppression and/or time to virological failure.

Conclusion: This study supports current Australian HIV clinical care as providing equivalent standards of care for male and female HIV-positive patients. In line with Australian epidemiology, the proportion of women in AHOD was low. However, we are currently addressing this by targeting the recruitment of women.

Table 1. Patient characteristics by sex.

		Female	Male	P-value
Number of patients		210	3,285	
Age at enrolment (years)	Mean Median (IQR)	36.4 34.1 (30.0-42.8)	40.7 39.5 (33.3-46.9)	<0.0001
Patient care setting, n (%)	General practice Hospital Sexual health clinic	53 (25) 53 (25) 104 (50)	1,240 (38) 733 (22) 1,312 (40)	0.001
Year of ART start, n (%)	1996-2004 2005-2011 ART naïve	127 (60) 53 (25) 30 (15)	2,216 (67) 675 (21) 394 (12)	0.11
CD4 cell count at ART initiation	Mean Median (IQR)	337 285 (190-420)	345 310 (170-475)	0.72
Plasma viral load at ART initiation	Mean Median (IQR)	75,757 4,295 (400-60,511)	147,152 14,665 (500-100,000)	0.006

Table 2. Clinical end-point univariate- and covariate-adjusted Cox proportional hazard ratios.

End-point	Hazard ratio (female vs male)	95% confidence interval	P-value
All-cause mortality			
Univariable	0.89	0.51-1.55	0.67
Multivariable*	0.98	0.56-1.75	0.97
AIDS illness			
Univariable	0.76	0.39-1.48	0.42
Multivariable*	0.75	0.38-1.48	0.41
All-cause mortality and AIDS illness (combined)			
Univariable	0.70	0.43-1.14	0.16
Multivariable*	0.74	0.45-1.21	0.23

^{*} Adjusted for age at cohort enrolment, injecting drug use (IDU) HIV exposure, hepatitisCvirus (HCV), hepatitisBvirus (HBV), recent CD4 cell count, recent HIV viral load@100 000 copies mL-1, year of cohort enrolment, number antiretroviral therapy (ART) modifications and clinical care setting.

Figure 1. Cumulative incidence of all-cause mortality comparing females and males participating in the Australian HIV Observational Database (AHOD).

^{1.} First ART defined as a combination of 3 or more antiretroviral agents and a duration of ART>14 days. Includes retrospective and prospective data. ATRAS sub study participants were excluded from analysis.

Figure 3: Empirical CD4 cell count distribution (boxplot) at antiretroviral therapy initiation by year of ART initation 1-3 (median CD4 indicated by horizontal grey bar)

^{1.} First ART defined as a combination of 3 or more antiretroviral agents and a duration of ART>14 days. Includes retrospective and prospective data. ATRAS sub study participants excluded from analysis.

^{2.} CD4 cell count selected from the observation closest to ART start date within a timeframe window of 12 months prior to ART start date and 1 month post ART start date.

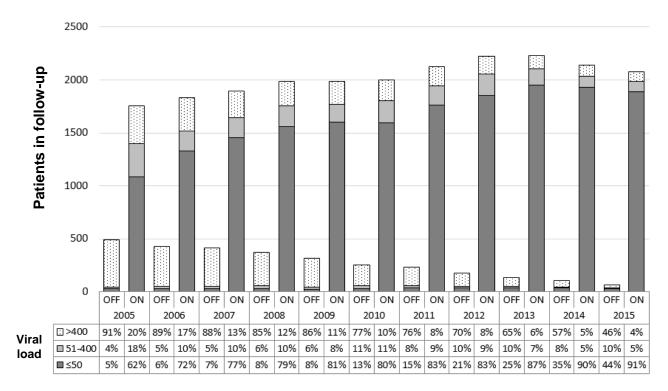

^{3.} A patient was excluded from the analysis if an undetectable viral load was recorded prior to initiating ART or was missing a viral load measurement prior to initiating ART.

^{4.} Includes data reported from 1 January 2014 to 31 March 2016.

^{2.} CD4 cell count selected from the observation closest to ART start date within a timeframe window of 12 months prior to ART start date and 7 days post ART start date.

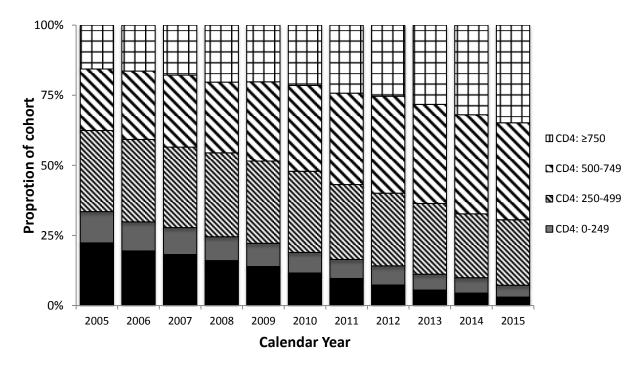

^{3.} A patient was excluded from the analysis if an undetectable viral load was recorded prior to initiating ART or was missing a viral load measurement prior to initiating ART.

Figure 4: Proportion of patients with an undetectable viral load, by treatment status (off /on treatment) and year¹

- Off treatment if never on a regimen of duration greater than 14 days for given calendar year. Viral load taken as median
 value during regimen of longest duration for given calendar year.
- * In the "off-treatment" group (n=61 in 2015), there are patients where their viral load time series is strongly indicative of the patient receiving therapy, defined as 2 or more recent records where pVL <50 copies/ml. <u>Data validation is ongoing</u> with sites.

Figure 5: CD4 cell counts (cells/µl) in patients receiving treatment by calendar year¹⁻³

- 1. Includes patients with a prospective CD4 measure during the relevant calendar year.
- 2. For patients on treatment, analysis based on the initial treatment intent, not on treatment administered (ITT), i.e. no adjustments are made for off-treatment following ART initiation.
- 3. Patients off treatment include those who have enrolled and have not initiated combination antiretroviral therapy.

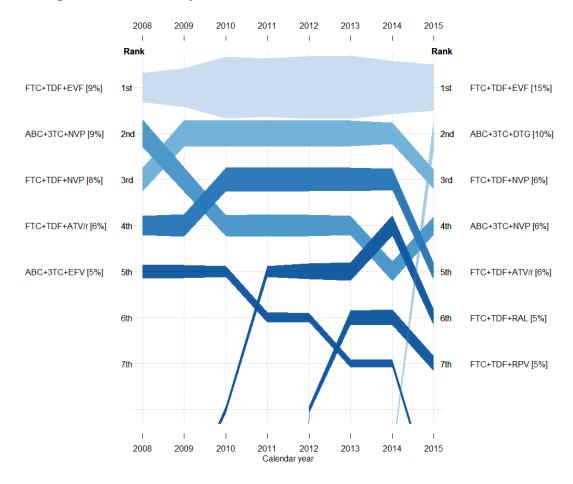

Table 9: Top ten treatment combinations among the AHOD cohort¹: January-December 2015

In 2015, there were a total of 397 unique antiretroviral treatment (ART) combinations among the 2352 AHOD patients on combination ART. A total of 2844 combination regimens were recorded among these patients throughout 2015. The top ten most common ART combinations are described below.

ART combinations	Number of regimens recorded during 2015
emtricitabine+tenofovir+efavirenz	417
abacavir+lamivudine+dolutegravir	274
emtricitabine+tenofovir+nevirapine	175
abacavir+lamivudine+nevirapine	165
emtricitabine+tenofovir+atazanavir+ritonavir	160
emtricitabine+tenofovir+raltegravir	144
emtricitabine+tenofovir+rilpivirine	139
emtricitabine+tenofovir+dolutegravir	107
emtricitabine+tenofovir+Elvitegravir+Cobicistat	98
abacavir+lamivudine+efavirenz	66

^{1.} Includes retrospective and prospective data. Combinations include 3 or more antiretroviral drugs. Fixed dose combinations are separated into individual component antiretroviral drugs.

Figure 6: Top five treatment combinations among the AHOD cohort¹ ranked by proportion² of total ART regimens recorded in years 2008-2015

^{1.} Includes retrospective and prospective data. Combinations include 3 or more antiretroviral drugs. Fixed dose combinations are separated into individual component antiretroviral drugs.

^{2.} Proportion defined as frequency of ART line divided by total number of ART regimens recorded. For example, 2015 Rank 1 proportion calculated by 417/2844=14.66%. Thickness of line over time is proportional to calculated percentage.

MONITORING DISPENSED ANTIRETROVIRALS VIA THE \$100 PROGRAM

Table 11 reports the number of people dispensed antiretroviral (ARV) treatment through the Australian Government's Highly Specialised (HSD) (s100) program. Data up to and including 2013 were based on data reported in the Public Health Dispensed National Patient report. The number of patients who were dispensed antiretroviral drugs per state per financial year quarter were analysed together with data on ARV use from the AHOD sample.

For the time period 2009 – 2013, to estimate the number of patients receiving ART, we combined data on the proportion of patients receiving certain mutually exclusive ARVs in AHOD with data from the \$100 program on the total number of people receiving the same ARVs. For example, lamivudine and emtricitabine are a common component of combination ART regimens in Australia, but should not be prescribed in combination. We calculated the proportion of all treated patients in AHOD who received lamivudine or emtricitabine as part of an ART regimen by year and state. We also estimated the total number of patients dispensed lamivudine or emtricitabine for HIV infection each year through the \$100 program by calculating the average number of patients prescribed each drug from the corresponding four financial year quarters. An estimate of the total number of people receiving any ART was then obtained by dividing the total number of patients receiving lamivudine or emtricitabine through the \$100 program by the proportion of treated patients in AHOD receiving the same ARV drugs.

Note: Prior to 2009, the HSD Report provided prescribed patient numbers by each antiretroviral agent. However after noting some inconsistencies with their methodology, they have since ceased providing these numbers. For years 2009-2010, instead we (The Kirby Institute) evaluated patient numbers by using a combination of total packs dispensed and an average "packs-per-patient" adjustment ratio. The packs-per-patient adjustment figure was calculated from 2008 data, where total packs dispensed and patient numbers were available. However, due to the relatively recent diversification of pack sizes, newer dosing schedules and the introduction of antiretroviral agents that were absent in 2008, we are uncertain as to how our packs-per-patient adjustment ratio has changed over time. Therefore we caution our estimates for 2011- 2013 data for Table 11.

From 2014 onwards, we report the number of people receiving ART based on a 10% sample of the Pharmaceutical Benefits Scheme (PBS) data, including \$100 drugs. Data on dispensed prescriptions for a PBS 10% sample is updated every quarter and supplied to a number of approved users or clients including Prospection which provides a dashboard interface (PharmDash) for querying the PBS 10% sample [1, 2]. The 10% sample of the PBS is a randomised patient level, de-identified PBS script claims data set from 2006-present. Currently the data set has 170 million script claims and 3 million patients. It includes all PBS listed drugs with HIV indications. The presented figures are annual totals of unique patients in December each year. This represents total number of patients obtaining at least one prescription for the indicated drug anytime during a year. This methodology is preferable due to increased accuracy of the source data and the removal of assumptions and extrapolations previously required. This may also explain the considerable increase in estimated number of patients receiving ART from 2013 to 2014.

^{1.} For 2010 to 2013 the number of people dispensed each antiretroviral drug during a calendar year was estimated by calculating the average of the total number of people dispensed each drug during the corresponding financial year quarters. Number of person years for July - December 2009 to December 2012 estimated from the HSD Program Public Hospital Dispensed National Pack Number Report because of changes to \$100 data collection methodology. Number of person years for 2013 estimated from the PBS item reports on services and benefits. 2. Dashes (-) indicate that data were not available.

^{3.} PharmDash [http://www.prospection.com.au/, 2 August 2016]

^{4.} Total patients calculated as (Lamivudine + Combivir (Lamivudine & Zidovudine)+Trizivir (Abacavir, Lamivudine & Zidovudine)+Kivexa (Abacavir & Lamivudine)+Emtricitabine +Truvada(Tenofovir & Emtricitabine) + Atripla(Tenofovir & Emtricitabine & Efavirenz) + Exiplera(Tenofovir & Emtricitabine & Rilpivirine))/the proportion of patients in the Australian HIV Observational Database receiving any of the previously mentioned drugs in each year. Estimates of total patients are rounded to nearest 100 patients.

^{5.} Public Hospital Expenditure until 2013, PBS + patient contributions thereafter.
